Abstract — The influence of the material inclusions on the input impedance of the loaded dipoles excited by a delta function is analytically investigated. Novel and accurate analytical expressions for the input impedance of the loaded dipoles are proposed based on the mode matching technique. The boundary conditions are also enforced to obtain several simultaneous equations for the discrete modal coefficients inside the radiating region. Study of the input impedance of the whole multilayered structure is accomplished by the cascade connection of mediums as characterized by their constitutive parameters. The derived formulas are successfully validated through a proper comparison with the results obtained with the commercial software CST Microwave Studio.

Index Terms — Loaded dipole, mode-matching.

I. INTRODUCTION
In recent years, the introduction of metamaterials (MTMs) opened the way for many research groups to enhance antenna performances. Due to unique electromagnetic properties, MTMs have been widely considered in monopole and dipole antennas to improve their performance [1-5]. The problem of dielectric loaded wire antenna is heretofore analyzed using numerical methods, e.g., method of moment (MoM) [6], finite difference time domain (FDTD) [7], and simulations based on commercial software [8]. However, the analytical analysis of the dielectric loaded dipole antennas has not been reported in the literature.

The novelty of this paper is to introduce a mode-matching analysis of a dipole antenna loaded with material inclusions. The concept of the MTM loaded dipole is very important and, as to the authors’ best knowledge, there are no papers reporting analytical expressions and full-wave analysis of this class of loaded antennas. In this paper, a theoretical formulation for a multiply dielectric loaded slotted spherical antenna is proposed based on the mode-matching method, to predict the behavior of the loaded dipole. It is worth noting that the radiation pattern of a finite length small angle biconical antenna differs only slightly from the pattern of a dipole [9]. Here, since the biconical antenna can be exactly analyzed and it also reduces, in the limiting case, to a cylindrical dipole antenna [10], this structure is considered for the analytical investigations. The obtained analytical formulas confirm the general conclusions recently presented in [7, 8], regarding the effect of material inclusions on the dipole antenna performance. It is demonstrated that the inclusion influence on the input impedance of a dipole is significant only for double-negative (DNG) MTM inclusions. The analytical results have been successfully validated through a comparison with the numerical results. The CST MICROWAVE is adopted for the simulations.

II. FIELD ANALYSIS
Figure 1a, illustrates a slotted dielectric loaded hollow conducting sphere of radius a, containing a Hertzian dipole $J = \mathcal{J} \delta(r - r')$, placed at the center ($r = r'$, $\theta = 0, \varphi$), here $(r, \theta, \varphi)$ are the spherical coordinates and $\delta$ is a delta function. The time convention is $e^{-j\omega t}$ suppressed throughout. Due to
azimuthally symmetry, the fields depend on \((r, \theta)\) and the fields are then TM waves, which can be expressed in terms of magnetic vector potentials. The total magnetic vector potential for the unslotted sphere (First region, I) is a sum of the primary and secondary magnetic vector potentials, [11].

\[
A' (r, \theta) = 2A''_0 (r, \theta) + \hat{r} A'_0 (r, \theta),
\]

while, the primary magnetic vector potential is a free-space Green’s function as

\[
A''_0 (r, \theta) = \frac{\mu_0 J_0 (kr)}{4\pi r},
\]

\(\hat{z}\) and \(\hat{r}\) are the unit vectors and \(R = \sqrt{r^2 + r'^2 - 2rr' \cos \theta}\). And the secondary magnetic vector potential is

\[
A'_0 (r, \theta) = \sum_{n=0}^{\infty} a_n \tilde{J}_n (kr) P_n (\cos \theta),
\]

where \(\tilde{J}_n (kr)\) and \(P_n (\cos \theta)\) are the spherical Bessel and Legendre functions, respectively, and [11]

\[
a_n = \frac{\mu_0 k J_n (kr) 2n + 1}{8\pi J_n (kR) n(n + 1)} \int_0^\infty \varphi \left( \varphi \left( \frac{\partial P_n (\cos \theta)}{\partial \theta} \right) \sin^2 \theta d\theta \right.
\]

\[
\left. \right| \begin{array}{c}
\left( a^2 - 2r^2 + ar' \cos \theta \right) \left( ik \hat{R} - 1 \right) \\
+ k^2 \hat{R}^2 \left( a^2 - ar' \cos \theta \right)
\end{array}
\]

Now consider a slotted conducting sphere, as shown in Fig. 1a. The total magnetic vector potential in region (I) consists of the incident \(A'\) and scattered \(A''\) potentials as

\[
A'_0 (r, \theta) = \sum_{n=0}^{\infty} C_n \tilde{J}_n (kr) P_n (\cos \theta).
\]

Here, \(C_n\) is an unknown modal coefficient. The \(r\)-component of the magnetic vector potential in region (II, III, IV, and V) of the \(l\)-th slot is

\[
A'_l (r, \theta) = \sum_{v=0}^{\infty} R_{v}^l (\cos \theta) \left[ D_{v}^l \tilde{J}_{v} (kr) + E_{v}^l \tilde{N}_{v} (kr) \right]
\]

where \(v = II, III, IV, V\) and

\[
R_{v}^l (\cos \theta) = \begin{cases} 
Q_{v}^l (\cos \theta) & v = 0 \\
Q_{v}^l (\cos \alpha') P_{v}^l (\cos \theta) - P_{v}^l (\cos \alpha') Q_{v}^l (\cos \theta) & v \geq 1 \\
P_{v}^l (\cos \theta) + G_{v}^l Q_{v}^l (\cos \theta) & III, IV
\end{cases}
\]

The \(r\)-component of the magnetic vector potential in region (VI) is

\[
A''_V (r, \theta) = \sum_{v=0}^{\infty} F_{v} \tilde{H}^l_v (kr) r P_{v} (\cos \theta),
\]

where \(F_{v}\) is an unknown modal coefficient and \(\tilde{H}^l_v (kr)\) is the spherical Hankel function of the second kind.

Fig. 1. (a) Multiply- (b) single slotted dielectric loaded conducting hollow sphere, and (c) dielectric loaded dipole antenna: cross-sectional view, \(a=0.1\text{mm}, b=2.5\text{mm}, h=|c-b|=0.5\text{mm}, d=5\text{mm}, r_0=0.1\text{mm}, H=2.4\text{mm}, L_d=4.9\text{mm},\) and the dipole radius, \(r_{d}\), is equal to 0.1\text{mm}.
To determine the modal coefficients, we enforce the field continuities as Table 1.

### Table 1: Boundary conditions

<table>
<thead>
<tr>
<th>Layer</th>
<th>Electric Field</th>
<th>Magnetic Field</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>I, II</td>
<td>( \varepsilon_0 = \varepsilon_1 ) ( \varepsilon_0 ) otherwise</td>
<td>( \hat{E}<em>\phi + H^I</em>\phi = H^\omega_\phi )</td>
<td>( r = a )</td>
</tr>
<tr>
<td>II, III</td>
<td>( \varepsilon_0 = \varepsilon_1 ) ( \varepsilon_0 ) otherwise</td>
<td>( H^\omega_\phi = H^\omega_\phi )</td>
<td>( r = b )</td>
</tr>
<tr>
<td>III, IV</td>
<td>( \varepsilon_0 = \varepsilon_1 ) ( \varepsilon_0 ) otherwise</td>
<td>( H^\omega_\phi = H^\omega_\phi )</td>
<td>( r = c )</td>
</tr>
<tr>
<td>VI, IV</td>
<td>( \varepsilon_0 = \varepsilon_1 ) ( \varepsilon_0 ) otherwise</td>

</tr>
</tbody>
</table>

Applying orthogonal integrals and mathematical manipulation some can write the equations as follow, [18]

\[
C_s = \frac{\mu_0 \varepsilon_1}{4\pi} \frac{2n+1}{\mu_0 \varepsilon_{11}} 2n(n+1) J^T_{\phi}(k,a) F_{s}
\]

Finally, the unknown coefficients are

\[
C_n, D^m_r, E^m_r, D^m_r, E^m_r, D^m_r, E^m_r, D^m_r, E^m_r, F_r
\]

### III. NUMERICAL ANALYSIS

From the formulas presented in the previous section, it is straightforward to write short programs that illustrate the difference between the different types of material inclusions. To this aim, the cone angle of the biconical antenna is selected to be as small as possible, e.g., \( 2\alpha_1 = 2.5 \) degree. It should be noted that, based on [12-13], it is well known that the input impedance of a biconical antenna changes significantly by changing cone angle. Hence the input impedance of a biconical antenna is investigated with regards to its cone angle. The inverse radiation impedance \( Z_v \) for biconical antennas is given by [11]

\[
j\eta_1 \sin \alpha_1, \ln \left( \cot \frac{\alpha_1}{2} \right) \sum_{n=0}^{\infty} \left[ D^m_r \hat{J}_n(k_j b) \right] \frac{\partial R_{s,\phi}(\cos \theta)}{\partial \phi} = 0.
\]

The analytic simulations have been compared with the CST simulation results of an equivalent dipole antenna (radius, \( r_d \)). The results have been presented in Fig. 2. According to this figure, for the antenna radius \( r_d < 0.01 \lambda \) (biconical antenna \( 2\alpha_1 \leq 3.4 \) degree, with regards to \( f=25 \)GHz as main frequency) the loaded dipole may be considered as a limit case of a loaded biconical antenna (the
approximation meet numerical simulations with good agreement). The simulation parameters are: 
\( a = 0.1 \text{mm}, \ b = 2.5 \text{mm}, \ d = 5 \text{mm}, \ r_0 = 0.1 \text{mm}, \ H = 2.4 \text{mm}, \ L_d = 4.9 \text{mm}, \ \varepsilon_r = 2.2, \) and \( \mu_r = 1. \) For the radius \( 0.01 \lambda < r_d < 0.02 \lambda, \) the antenna input impedance has been extracted approximately, and larger values cause significant errors in impedance computations.

by Tai [14]. A slightly more general expression applicable to a biconical antenna embedded in a lossless material of arbitrary permeability and permittivity has been given by [15]. Assuming \( L = 1, \) the region III fills by PEC, and \( k_x \alpha \ll 1; \) the slotted sphere becomes a simple biconical antenna, (Fig. 3). In Fig. 4, the effects of the numbers of modes in computation convergence have been depicted. It is clear that good convergence has been achieved.

In Fig. 5, the analytic results for the return loss of a biconical antenna have been compared with CST simulation results. As it is stated before, the antenna cone angle is \( 2\alpha_1 = 2.5 \) degree. According to this figure, a good agreement has been achieved between analytic and numeric simulations.

**A. Dielectric-covered biconical antennas**

To validate the proposed method, it is useful to consider a conventional covered biconical antenna (Fig. 3) as the first limiting case. The input impedance of a thin biconical antenna embedded in dielectric material has been derived

\( r_0 = 0.1 \text{mm}, \ H = 2.4 \text{mm}, \ L_d = 4.9 \text{mm}, \ \varepsilon_r = 2.2, \) and \( \mu_r = 1. \) For the radius \( 0.01 \lambda < r_d < 0.02 \lambda, \) the antenna input impedance has been extracted approximately, and larger values cause significant errors in impedance computations.

by Tai [14]. A slightly more general expression applicable to a biconical antenna embedded in a lossless material of arbitrary permeability and permittivity has been given by [15]. Assuming \( L = 1, \) the region III fills by PEC, and \( k_x \alpha \ll 1; \) the slotted sphere becomes a simple biconical antenna, (Fig. 3). In Fig. 4, the effects of the numbers of modes in computation convergence have been depicted. It is clear that good convergence has been achieved.

In Fig. 5, the analytic results for the return loss of a biconical antenna have been compared with CST simulation results. As it is stated before, the antenna cone angle is \( 2\alpha_1 = 2.5 \) degree. According to this figure, a good agreement has been achieved between analytic and numeric simulations.

**B. Dielectric-loaded biconical antennas**

In order to demonstrate the capability of the MTM loading to realize a miniaturized antenna, two examples are studied here. The first one is a dipole antenna filled with double positive (DPS) material inclusions, \( (\varepsilon_r = 2.2 \text{ and } \mu_r = 1). \) A DNG-loaded dipole antenna, whose parameters are labeled in Fig. 1-c, is also studied.

Here, the Drude model [16] is used to simulate the MTM inclusions, since it can yield a negative real part of the permittivity/permeability over a wide frequency range. For the DNG inclusions, both \( \mu \) and \( \varepsilon \) obey the Drude model (with plasma frequency \( \omega_p = 15 \times 10^{10} \) rad/s and collision frequency \( f_c = 0.01 \text{GHz} \)) as

\[
\xi_r(\omega) = \xi_{\infty} - \frac{\omega_p^2}{\omega(\omega - i f_c)} \quad (18)
\]

It should be noted that, this selection has been affected by all the other relative parameters, e.g.,
In Fig. 6, the effects of the numbers of modes in computation convergence have been presented. Again, it is clear that good convergence has been obtained. The analytical and simulated results for the reflection coefficient of the DPS- and DNG-loaded dipole antennas are presented in Fig. 7. As can be seen from this figure, the analytical results for the reflection coefficient of a loaded dipole are in good agreement with the CST simulation results. Simulations show that for the dipole antenna loaded with DNG-inclusions, an additional resonance frequency is introduced at the frequencies lower than the antenna resonant frequency where the antenna radiates an omnidirectional radiation pattern.

In contrast, for the dipoles loaded with DPS-inclusions, changing DPS locations on the antenna arms causes no resonances at frequencies lower than the main resonant frequency. An important advantage of the proposed antenna is that the dipole length does not need to be increased to lower the resonant frequency. Consequently, a compact antenna is obtained. The proposed method, suggested a bandwidth of 0.3% at 2.2GHz (which is wider than the bandwidth of other miniaturized MTM loaded dipoles [1-2]) while it means 11.8 times frequency reduction with regards to resonance frequency of DPS loaded antenna (26GHz). Since changing the locations and dimensions of the DPS/DNG materials does not have any significant effect on the antenna radiation patterns, the proposed antennas radiate omnidirectional radiation patterns at all resonant frequencies. However, these are not plotted here for the sake of brevity.

**IV. CONCLUSION**

The behavior of a biconical/dipole antenna loaded with MTM inclusions has been examined both analytically and numerically. The theory is compared with different simulation results resulting in a very good agreement between them. The analytical investigations also reveal that embedding DNG-inclusions in a simple biconical/dipole antenna can provide an opportunity to design miniaturized antenna.
Fig. 7. $|S_{11}|$ [dB] of a (a) dielectric, and (b) DNG-loaded biconical antenna: analytical against numerical results. Analytical results are obtained using proposed analytical expressions; numerical results are computed by CST software.

ACKNOWLEDGMENT

The authors would like to thank Iran Telecommunication Research Centre (ITRC) for its financial supports.

APPENDIX

In Eqs. (9)-(15) the required definitions are defined as follow:

$$I_m = -a_i \frac{\partial}{\partial \theta} R_i (\cos \theta) \frac{\partial}{\partial \theta} P_i (\cos \theta) \sin \theta \sin \phi, \quad (A-1)$$

$$X^m = \left[ \frac{\mu_{m} e_{m}}{\mu_{m} e_{m}} \right] \sum_{n=1}^{\infty} \frac{2n+1}{2n(n+1)} \tilde{J}_n (k_{m} a) \tilde{J}_{n+1} (k_{m} a) I_m^m, \quad (A-2)$$

$$E^m = \left[ \frac{\partial}{\partial \theta} \left( \frac{e^{j \theta}}{R} \right) \right] R^m_j (\cos \theta) \sin \theta \sin \phi, \quad (A-3)$$

$$K^{\gamma \gamma'} = \left[ \frac{\partial}{\partial \theta} R^{\gamma \gamma'} (\cos \theta) \frac{\partial}{\partial \theta} R^{\gamma \gamma'} (\cos \theta) \sin \theta \sin \phi, \quad (A-4)$$

$$\begin{align*}
\left\{ \begin{array}{ll}
Q_0 (\cos \alpha) - Q_0 (\cos \alpha') & \quad \phi = 0 \\
\varepsilon (z + i) \varepsilon R^{\gamma \gamma'} (\cos \theta) & \quad \phi \geq 1, \gamma = \gamma', \\
\varepsilon R^{\gamma \gamma'} (\cos \theta) & \quad \gamma = \gamma', \gamma' = \gamma + 1
\end{array} \right.
\end{align*}$$

$$K^{\gamma \gamma'} = \left[ \frac{\partial}{\partial \theta} R^{\gamma \gamma'} (\cos \theta) \frac{\partial}{\partial \theta} R^{\gamma \gamma'} (\cos \theta) \sin \theta \sin \phi, \quad (A-5)$$

$$\begin{align*}
\gamma^{\phi \phi'} = \left[ \frac{\partial}{\partial \theta} \left( \frac{e^{j \theta}}{R} \right) \right] R^{\gamma \gamma'} (\cos \theta) \sin \theta \sin \phi, \quad (A-6)
\end{align*}$$
